

7655 Rock Drill Failure Causes

What causes carbide failure in rock tools?

most certainly lead to carbide failure. In non-wearing rock formations 'snakeskin' fatigue is a primary factor in carbide failure if regular grinding intervals are not employed. This guide illustrates the main types of failure in rock tool products. Listed with each type of failure are the probable causes of the failure and some recommendations.

What causes a rig to fail?

Conditions that are causing the failure. It is suggested that the following be inspected for correct operation and handling, including proper bit grinding. Hole misalignment through poorly serviced rigs, bad collaring and wandering holes are the foremost factors contributing to stress in the drill.

What happens if you drill in non-abrasive rock?

Drilling in non-abrasive rock creates micro-fractures in the carbide sometimes looking like snake skin. The rock leaves a shiny surface. Use a softer carbide grade on the buttons and a fatigue in the surface of the cemented carbide, leading to button failure. Excessive button protrusion through incorrect grinding or steel wash.

What happens if a drill is worn out?

Replace any worn out parts, following manufacturer's recommended discard limits closely. Snake skin is a wear pattern of micro cracks that develop from drilling fatigue in non-abrasive rock. The cracks will eventually penetrate deeper and cause large chunks to break away, see F8, F9, F12, & F13.

How do you re-grind a rock drill?

Adjust drilling pressures. Regrinding should be done when the wear flats are max. 1/3 of the button diameter. Monitor coupling temperatures and adjust feed pressures according to recommendations. Adjust rotation speed. Use Retrac bits and activate anti-jamming when drilling. Use a rock drill with power extractor.
