What is rock cut slope design?

Rock cut slope design considers the structural characteristics and strength properties of rock masses to develop designs that address constructability and long-term performance. The primary goal of a rock cut slope evaluation and design is to determine the steepest stable cut slope angle for a continuous slope, without intermediate slope benches.

What is a rock slope exploration & design?

A rock slope exploration and design will be for either a new rock cut or an existing cut that will be rehabilitated or reconfigured to meet the goals of an ODOT project. New rock cuts are excavated in areas where there typically are limited (if any) rock exposures, and therefore, a detailed subsurface exploration is required.

What is the purpose of a rock slope design process?

The purpose of the rock slope design process is to design and construct rock cuts that will be stable and provide long-term safety for the public. The inclination of rock slopes should be based on the structural geology and stability of the rock units. Rock slopes of vertical, 3V on 1H, 2V on 1H, 3V on 2H and 1V on 1H are used at NYSDOT.

How do I calculate excavation slope?

Simply input the vertical depth of the excavation and the desired slope ratio (e.g., 1.5 for a 1.5:1 slope), and the calculator will provide the horizontal distance needed from the edge to the bottom of the slope. What is Excavation Slope? An excavation slope is the inclined surface created when digging into the ground to remove soil or rock.

What is exploration for a rock cut slope?

Exploration for a rock cut slope, which includes geologic explorations, data collection, and presentation of information, are vital to the design and construction of rock cut slopes. This section describes the required steps for the design of a new rock cut slope or the rehabilitation of an existing slope.

When is a rock slope created?

When a rock slope is created by an excavation required by a new alignment, a realignment of an existing road, or when a rock slope is addressed for safety reasons, the parameters of the rock will be discussed by the Project Designers with the Engineering Geologists.

What is directional drilling? Directional drilling is a broad term used to describe any boring that doesn't go in a straight line vertically down. In fact, ...

Distance between rock drill and slope

Rock Volume per Blast. In turn the Rock Volume is based on Width of the Blast, ...

Pre-mining geological structures, particularly fault planes, represent zones of potential weakness in the rock mass, and are therefore zones of potential slope failure, and should be taken into ...

One plan and section view for each rock cut excavation showing the proposed drill pattern for any blastholes, including blasthole spacing, blasthole diameters, blasthole angles, lift height, drill ...

Use our free Excavation Slope Calculator to determine OSHA-compliant safe angles and ratios for construction excavation. Get instant calculations based on soil type and depth for maximum ...

The distance between multiple encasements shall be the greater of either 24" or twice that of the diameter of the larger pipe being installed. Wing cutters when used shall only add a maximum ...

The distance between the HDD rig and the start of the steep slope was approximately 230 feet. This made an entrance angle of about 42 percent necessary to be ...

This distance should not be measured from the crown of the spoil deposit. This distance requirement ensures that loose rock or soil from the temporary spoil will not fall on employees ...

Drill and Blast (D& B) tunneling is a construction technique critical for excavating through solid rock and other resilient materials. This method is ...

uth then there will be changes in the calculation. Minimum curvature calculations assume that the arc is the shortest path to drill wells to meet on the second point of the survey on a small slope ...

Drill and Blast (D& B) tunneling is a construction technique critical for excavating through solid rock and other resilient materials. This method is especially pertinent in ...

Type C - Cohesive soil with an unconfined compressive strength of 0.5 tsf (48 kPa) or less, granular soils (including gravel, sand, and loamy sand), submerged soil or soil from which ...

Furthermore, this study assists mining practitioners in predicting the allowable number of blast events to prevent slope failure and recommends avoiding blast events with a ...

Historical perspective By far the most common technique of rock excavation is that of drilling and blasting. From the earliest days of blasting with black powder, there have been steady ...

Distance between rock drill and slope

Soil cuts are excavated along natural hillsides, through ridges and mesas, and into existing embankment. Any slope excavated into existing fill, alluvium, colluvium, residual soils, or weak ...

Understanding OSHA's Subpart P requirements for excavation slopes is crucial for workplace safety. Different soil types require different ...

The geometry of the slope is illustrated in Figure 5 which shows a 60 m high slope with three 20 m high benches. The overall slope angle is 50°; and the individual bench faces are inclined at 70°; ...

e) Drilling operations are to be progressed at a rate that will allow blasting operations to commence and be completed on time, without excessive sleep time as a result of drilling ...

suitable control measures are in place to protect people and vehicles from falling from faces (edge protection, safe working practices for drilling and charging in rock quarries, ...

The vertical distance between main levels is commonly 100, 125, or 150 feet, although intervals as low as 50 feet and as high as 250 or 300 feet ...

The way of reverse slope drilling in the BHRS improves the drilling efficiency and increases the inclination angle between production blastholes and slope. As the inclination ...
