What is the startup process and emergency shutdown of an air compressor?

What is The Startup Process and Emergency Shutdown of an Air Compressor's Motor? After pressing the motor's start button, the motor initiates operation. During this period, the motor is in the ramping or running phase. Meanwhile, the air compressor remains in an unloaded state.

Why does my compressor trip on over temperature?

If your compressor trips on over temperature, it could be any of the following: Ambient temperature too high or not enough ventilation. A screw compressor can run loaded ('pumping air') or unloaded ('idle'). The inlet/loading valve opens and closes according to air demand.

What should I do if my air compressor is too low?

If the capacity of the air compressor is really too low, check the following: Check differential pressure over oil separator. Replace separator when necessary. Check and replace compressed air filters (if installed). Compressor does not unload. Check if pressure switch is correctly set and working.

How do I know if my air compressor is working?

If you have a compressed air dryer, check the dewpoint. Check the current draw with a current clamp meter. If the motor draws excessive current: Try to turn the compressor by hand. It should be possible to turn it around. It should turn around smoothly, without any 'hiccups' (be sure to completely shut down the air compressor!).

What happens if a air compressor is overheating?

When the discharge temperature of the air compressor exceeds 100°C or the motor's thermal protection device activates due to overload, the power supply is cut off. The motor halts immediately, and the three-way solenoid valve and intake valve close. The blowdown valve fully opens, releasing the compressed air from the system into the atmosphere.
