

What happens if the rock drill leaks oil and gets too hot

Why is hydraulic oil overheating?

The system parts and components are wearing out and need to be replaced. The first cause of hydraulic oil overheating is when the hydraulic equipment system parts and components are nearing the end of their useful lifespans. As they degrade, due to increased internal leakage, they have to work harder to maintain the desired system pressure.

What happens if you don't consider the entire hydraulic system?

However, when you do not consider the entire system, it can cause the system to work hard, give off more heat, and increase hydraulic oil temperatures, leading to circuit overheating. For instance, you may want to increase the fluid flow rate through the system.

What happens if hydraulic fluid is contaminated?

The hydraulic fluid is contaminated. If there is dirt, sludge, debris, or water in the hydraulic fluid, the system will generate more heat as it attempts to compensate for the contaminants and push the fluid through the system.

Why is my hydraulic pump overheating?

For example, your hydraulic pump is wearing out and needs to be replaced. Due to internal wear, pressurized fluid escapes from the high pressure side to the low pressure side, generating heat and increasing the temperature of the hydraulic fluid and causing circuit overheating. #2.
